SCS 1214: Operating Systems

Dr. Dinuni Fernando, PhD

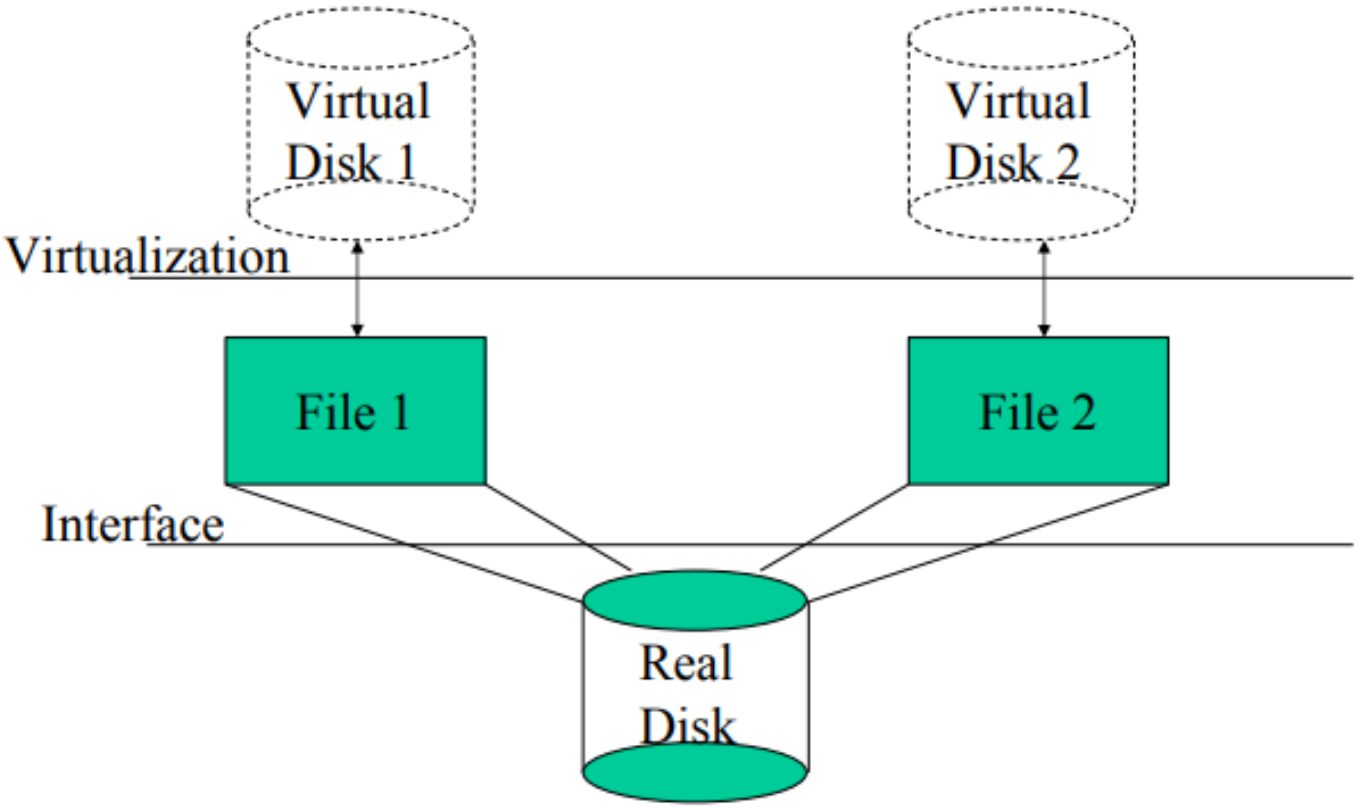
Based on “Virtual Machines” ,Smith and Nair, Chapter 1
Chapter 7, Andrew Tanenbaum's Operating systems concepts

Virtual Machines

Virtualization

- Makes a real system appear to be a set of virtual systems.
- Types of Virtualizations
  1. One-to-many virtualization
     - E.g. one physical machine may appear as multiple virtual machines
     - one physical disk may look like multiple virtual disk
     - one physical network may look like multiple virtual networks
  2. Many-to-one virtualization
     - Many physical machines/disks/networks may appear to look like one virtual machine/disk/network etc
  3. Many-to-many virtualization
     - Extend the above statements.

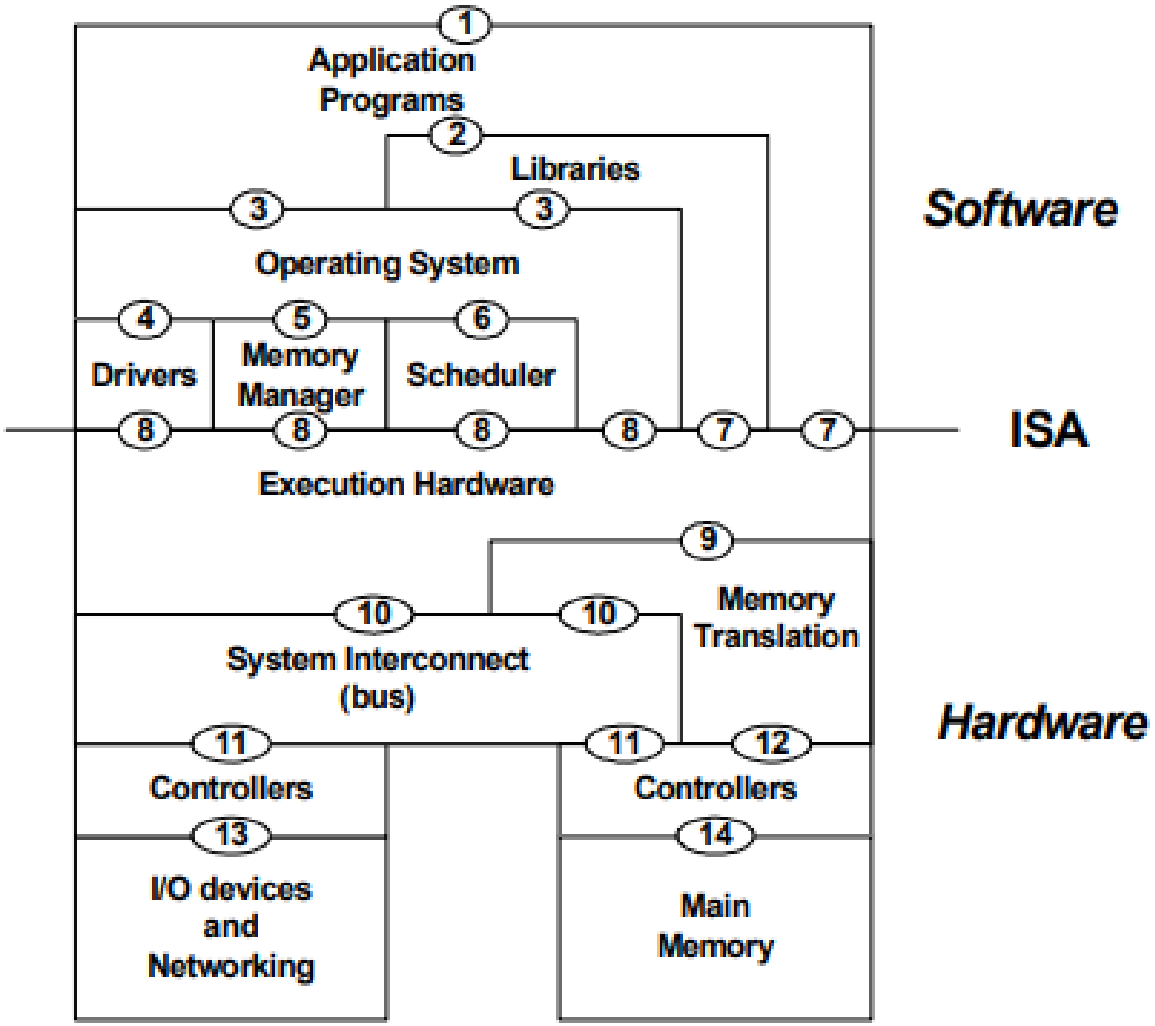
Eg: Disk Virtualization



Virtual Machines

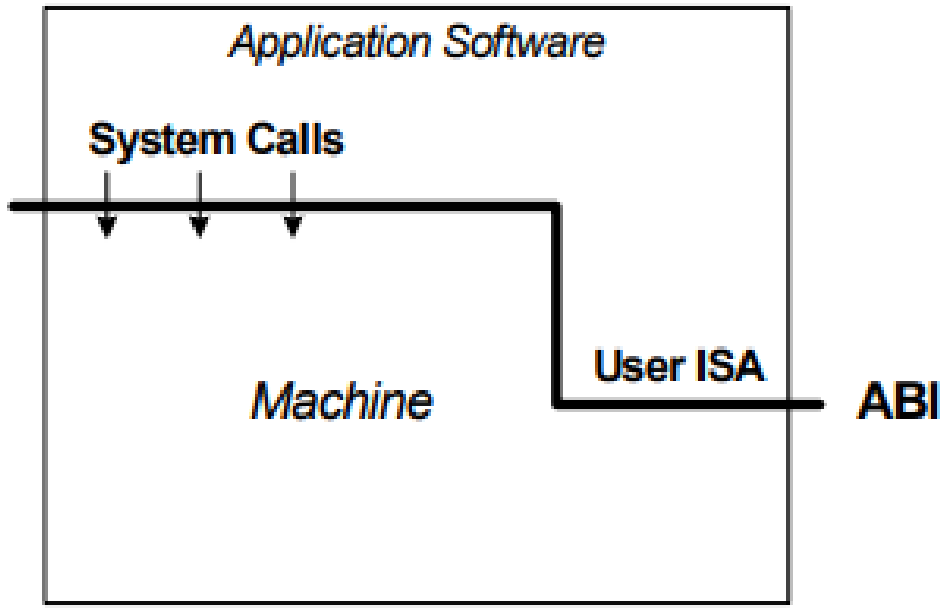
- Logical/Emulated representations of full computing system environment
  - CPU + memory + I/O
  - Implemented by adding layers of software to the real machine to support the desired VM architecture.
- Uses:
  - Multiple OSes on one machine, including legacy OSes
  - Isolation
  - Enhanced security
  - Live migration of servers
  - Virtual environment for testing and development
  - Platform emulation
  - On-the-fly optimization
  - Realizing ISAs not found in physical machines

Interfaces of a computer system

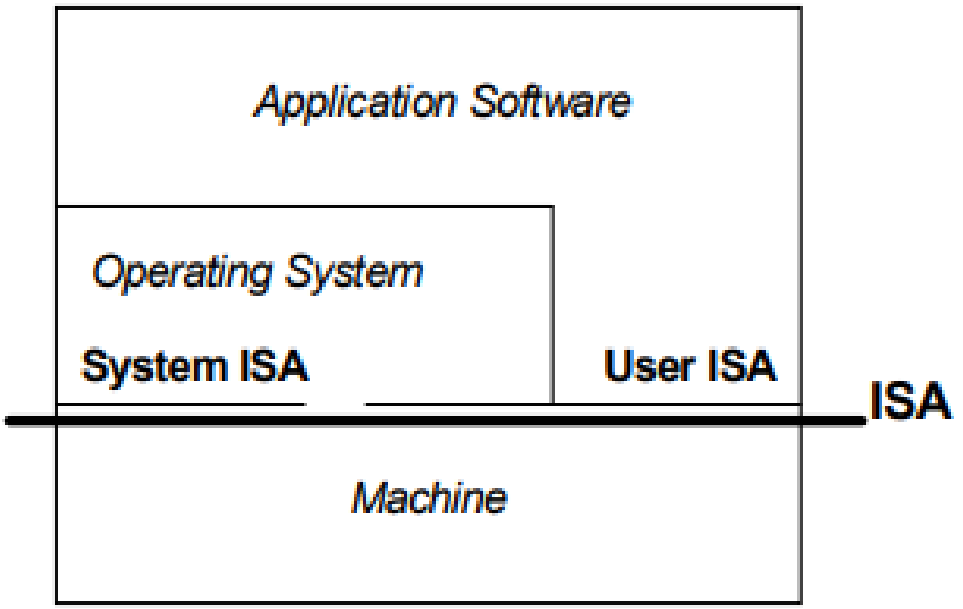


User ISA : 7
System ISA : 8
Syscalls : 3
ABI : 3,7
API : 2,7

Machine Interfaces



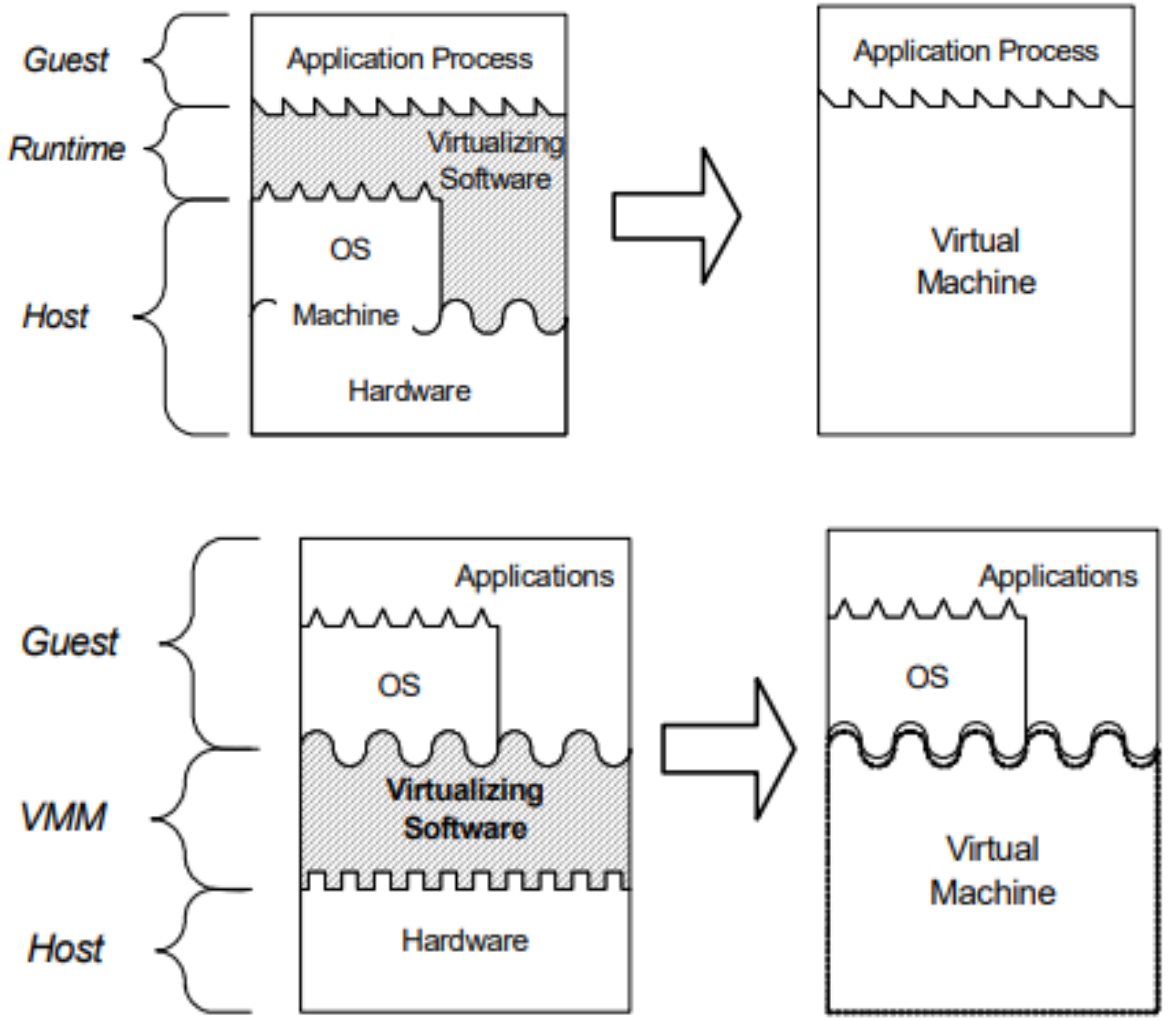
(a)



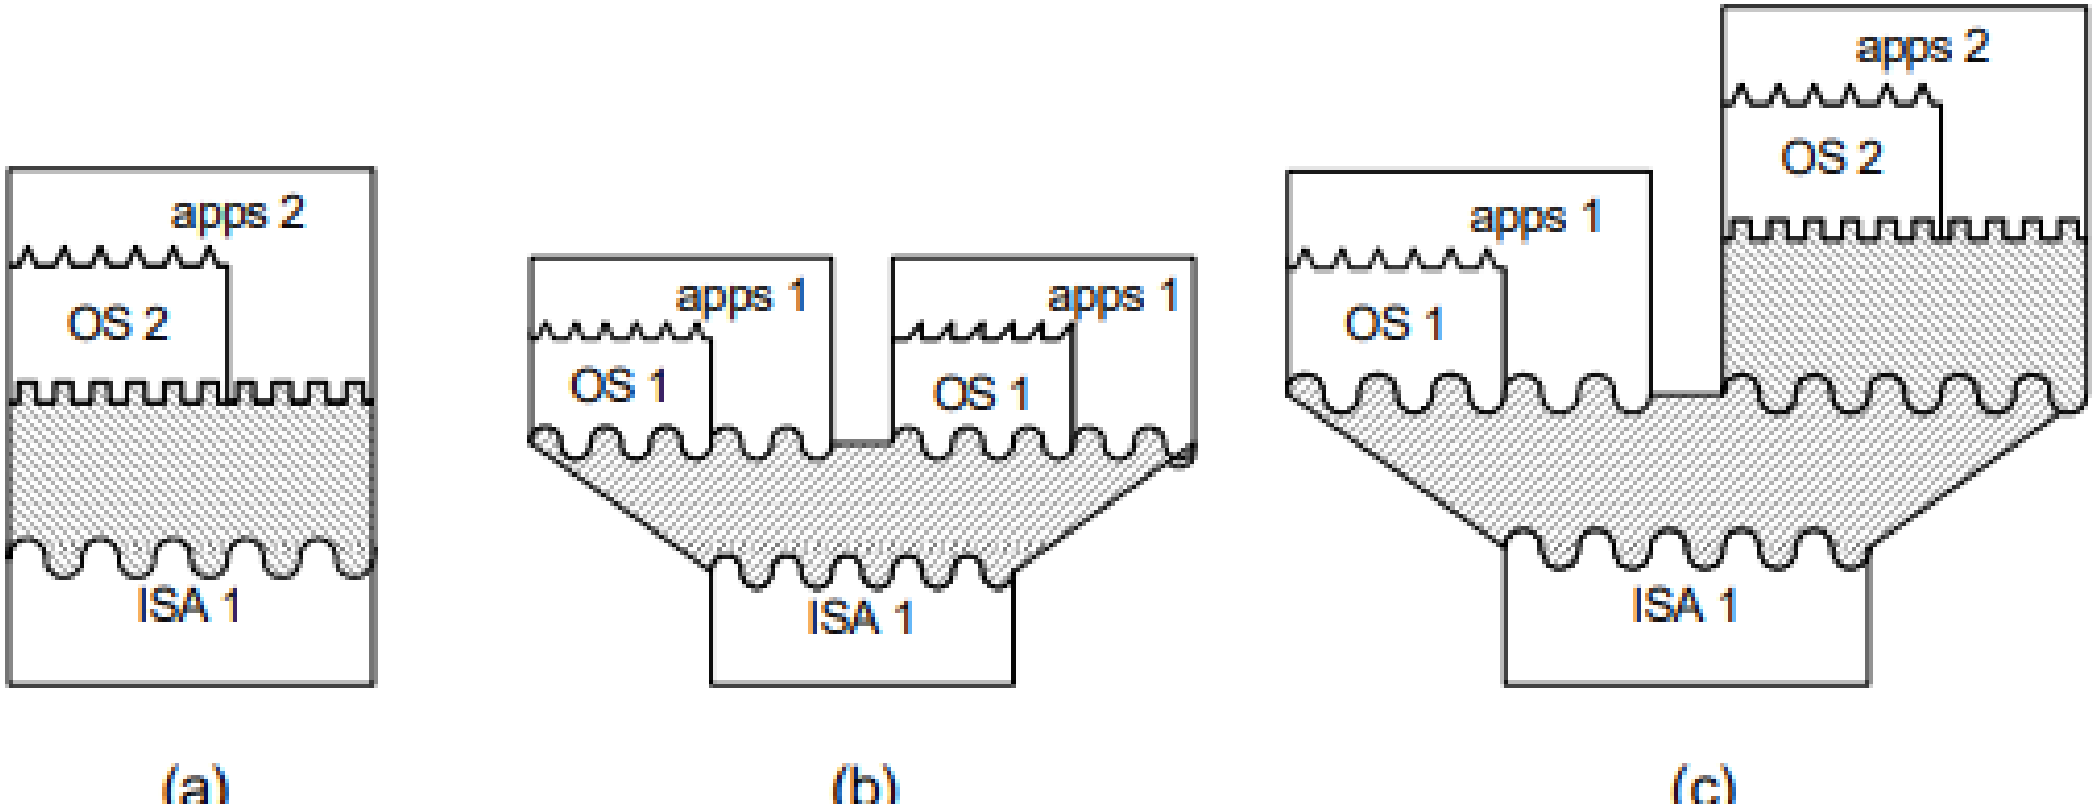
(b)

Types of VMs

- Process VMs
  - Virtualizes the ABI
  - Virtualization software = Runtime
    - Runs in non-privileged mode (user space)
    - Performs binary translation.
  - Terminates when guest process termina
- System VMs
  - Virtualizes the ISA
  - Virtualization software = Hypervisor
    - Runs in privileged mode
    - Traps and emulates privileged instructi
  - Lasts as long as physical host is alive

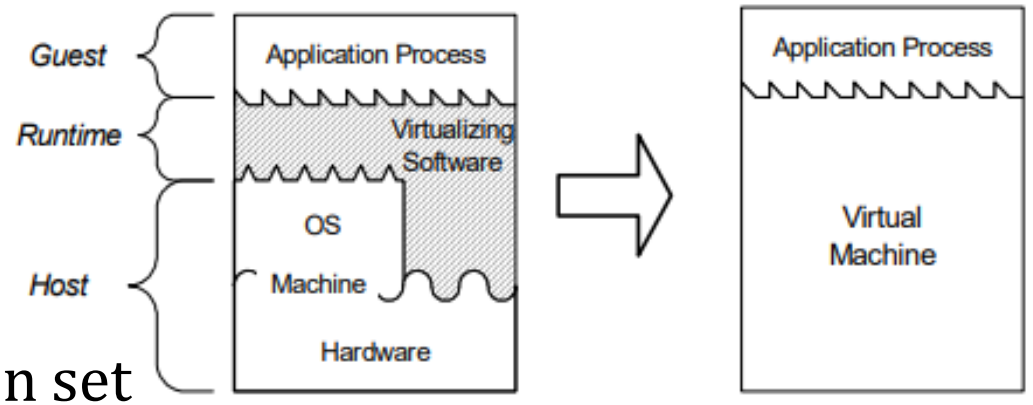


Uses of Virtualizing Software

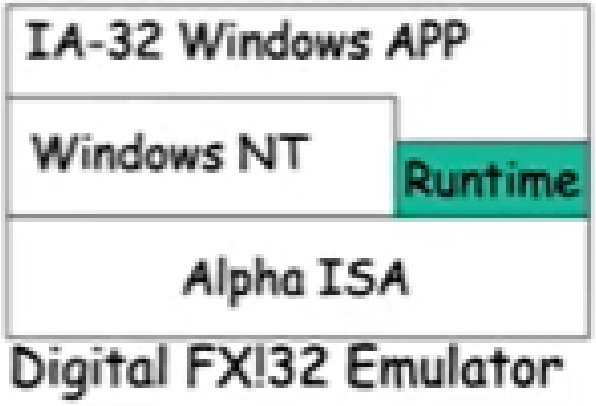


a) emulating one instruction set with another
b) replicating a virtual machine so that multiple OSes can be supported simultaneously,
c) composing virtual machine software to form a more complex, flexible system.

Process Virtual Machines

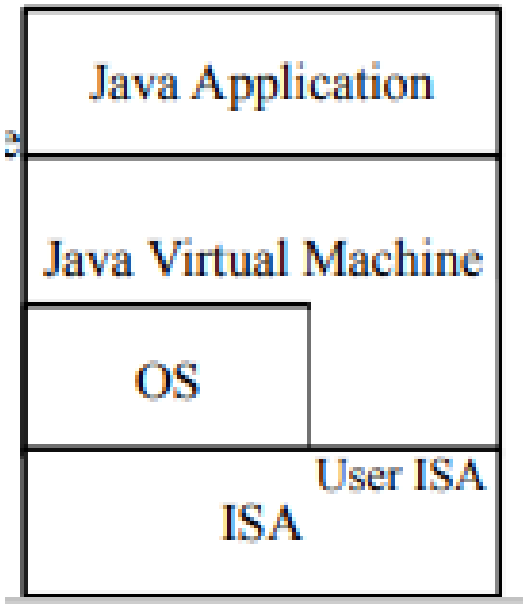


- Process in a multiprogramming OS
  - Standard OS syscall interface + instruction set
  - Multiple processes, each with its own address space and virtual machine view.
- Emulators
  - Support one ISA on hardware designed for another ISA
  - Interpreter:
    - Fetches, decodes and emulates individual instructions. Slow.
  - Dynamic Binary Translator:
    - Blocks of source instructions converted to target instructions.
    - Translated blocks cached to exploit locality.



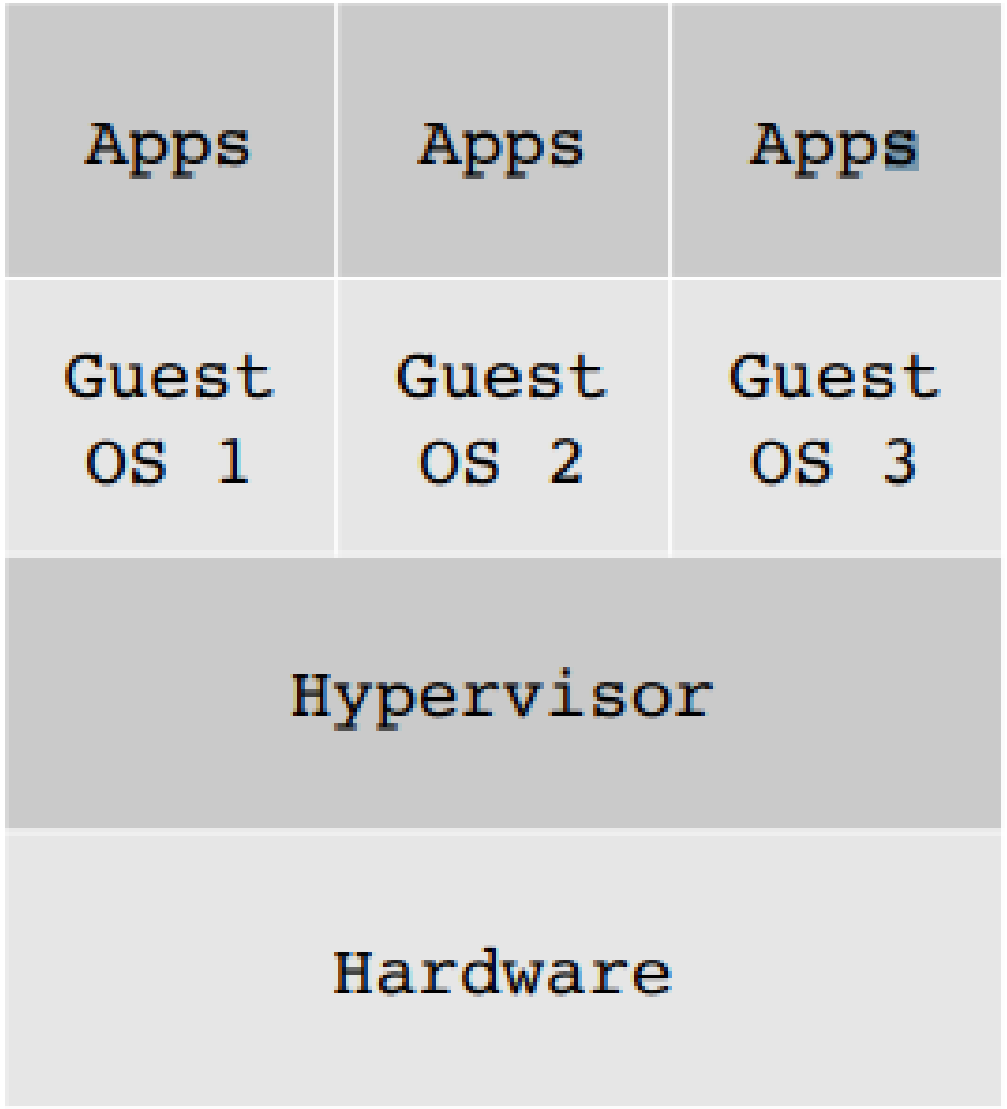
Process Virtual Machines (cont'd)

- Same ISA Binary Optimizers
  - Optimize code on the fly
  - Same as emulators except source and target ISAs are the same.
- High-Level Language VMs
  - Virtual ISA (bytecode) designed for platform independence
  - Platform-dependent VM executes virtual ISA
  - E.g. Sun's JVM and Microsoft's CLI (part of .NET)
  - Both are stack-based VMs



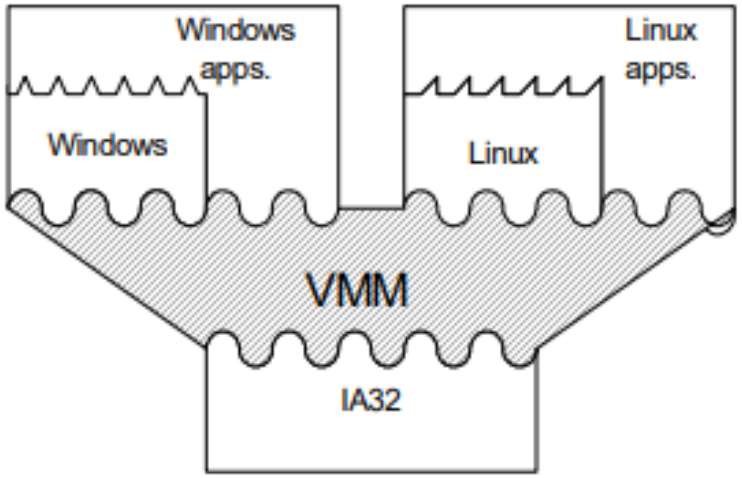
Hypervisor

- Also called Virtual Machine Monitor (VMM)
- A hypervisor is an operating system for operating systems
  - Provides a virtual execution environment for an entire OS and its applications
  - Controls access to hardware resources
  - When guest OS executes a privileged instruction, Hypervisor intercepts the instruction, checks for correctness and emulates the instruction.



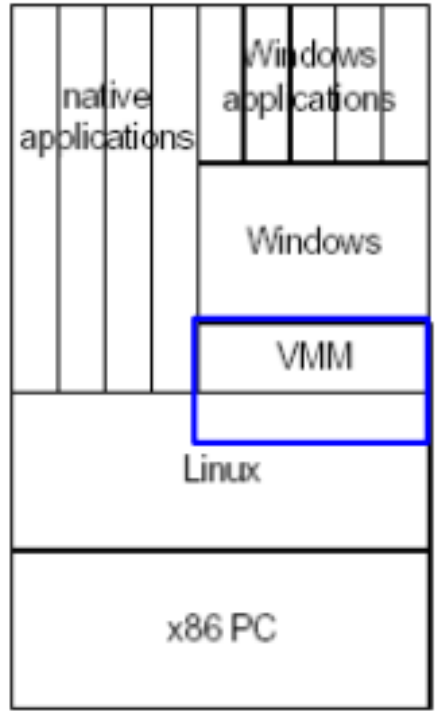
Type 1 Hypervisor (Classical System VMs)

- Hypervisor executes natively on the host ISA
- Hypervisor directly controls hardware and provides all device drivers
- Hypervisor emulates sensitive instructions executed by the Guest OS
- E.g. KVM and VMWare ESX Server



Type-2 Hypervisors (Hosted VMs)

- A host OS controls the hardware
- The Hypervisor runs partly in process space and partly in the host
- kernel
- Hypervisor relies on host OS to provide drivers
- E.g. VMWare Desktop Client



Para-virtualized VMs

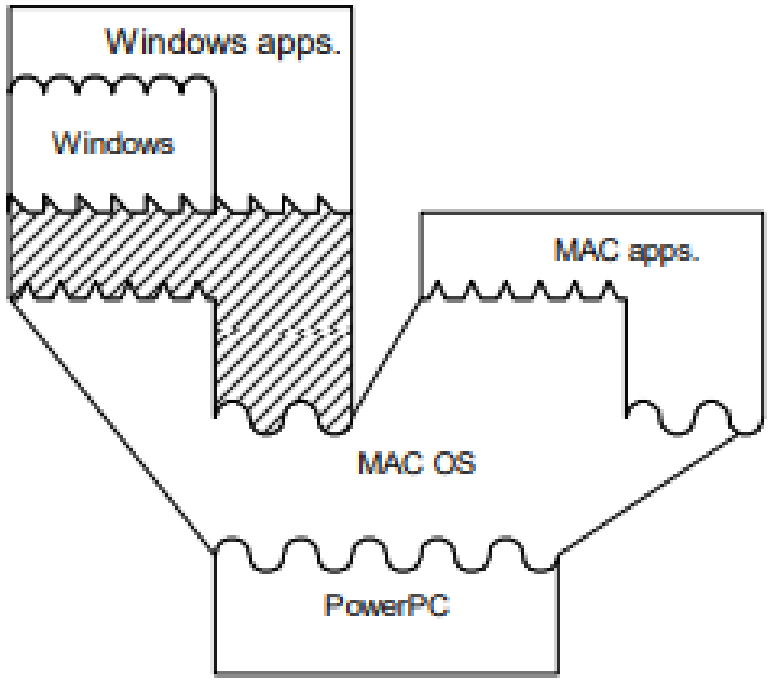
- Modify guest OS for better performance
  - Because “Trap and emulate” is expensive for many privileged instructions
- Para-virtualized VM sees a virtual hardware abstraction that is similar, but not identical to the real hardware.
- Guest OS is modified to replace some privileged instructions with “hypercalls” to the Hypervisor.
- Advantage: Results in lower performance overhead
- Disadvantage: Needs modification to the guest OS.
- E.g. Xen provides both para-virtual as well as full-virtualization
- Often traditional Hypervisors are partially para-virtualized
  - Device drivers in guest OS may be para-virtualized whereas CPU and Memory may be fully virtualized

Examples

Virtualizaton method	Type 1 hypervisor	Type 2 hypervisor
Virtualization without HW support	ESX Server 1.0	VMware Workstation 1
Paravirtualization	Xen 1.0	
Virtualization with HW support	vSphere, Xen, Hyper-V	VMware Fusion, KVM, Parallels
Process virtualization		Wine

Whole System VMs: Emulation

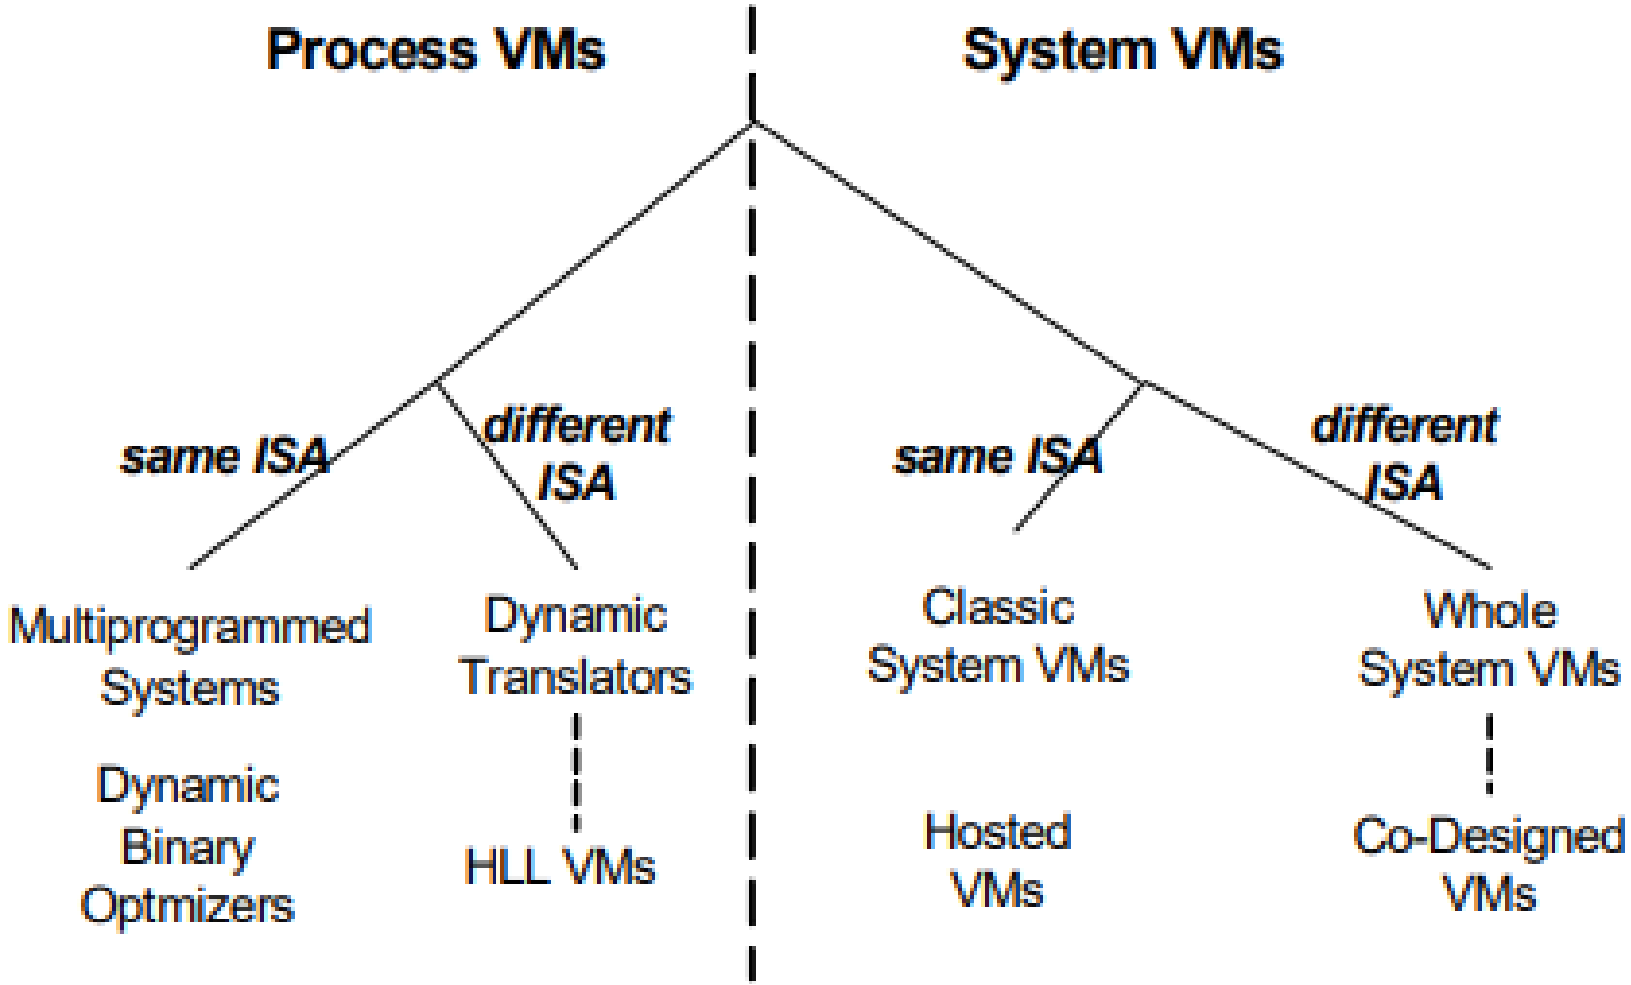
- Host and Guest ISA are different
- So emulation is required
- Hosted VM + emulation
- E.g. Virtual PC (Windows on MAC)



Co-designed VMs

- The hypervisor is designed closely with (and possibly built into) a specific type of hardware ISA (or native ISA).
- Goal: Performance improvement of existing ISA (or guest ISA) during runtime.
- Hypervisor performs Emulation from Guest ISA to Native ISA.
- E.g. Transmeta Crusoe
  - Native ISA based on VLIW
  - Guest ISA = x86
  - Goal power savings

Taxonomy



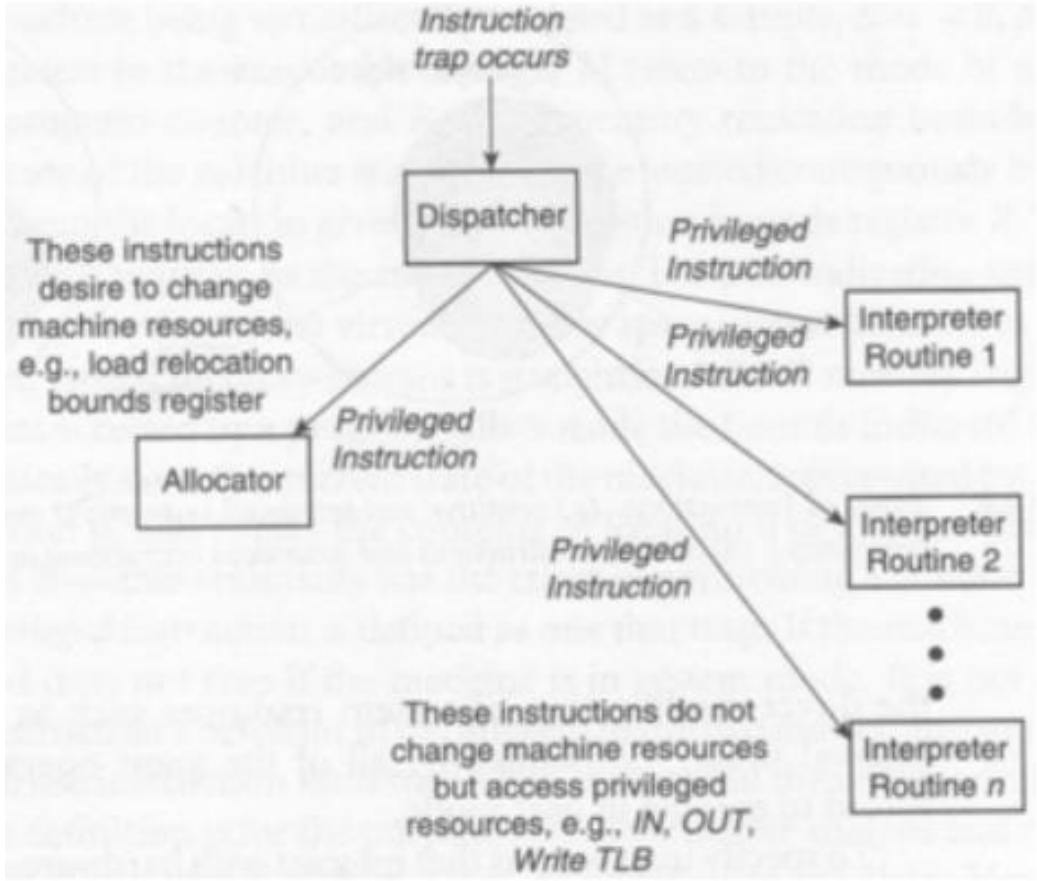
Process VMs
System VMs
same ISA
different ISA
same ISA
different ISA
Multiprogrammed Systems
Dynamic Translators
Classic System VMs
Whole System VMs
Dynamic Binary Optmizers
HLL VMs
Hosted VMs
Co-Designed VMs

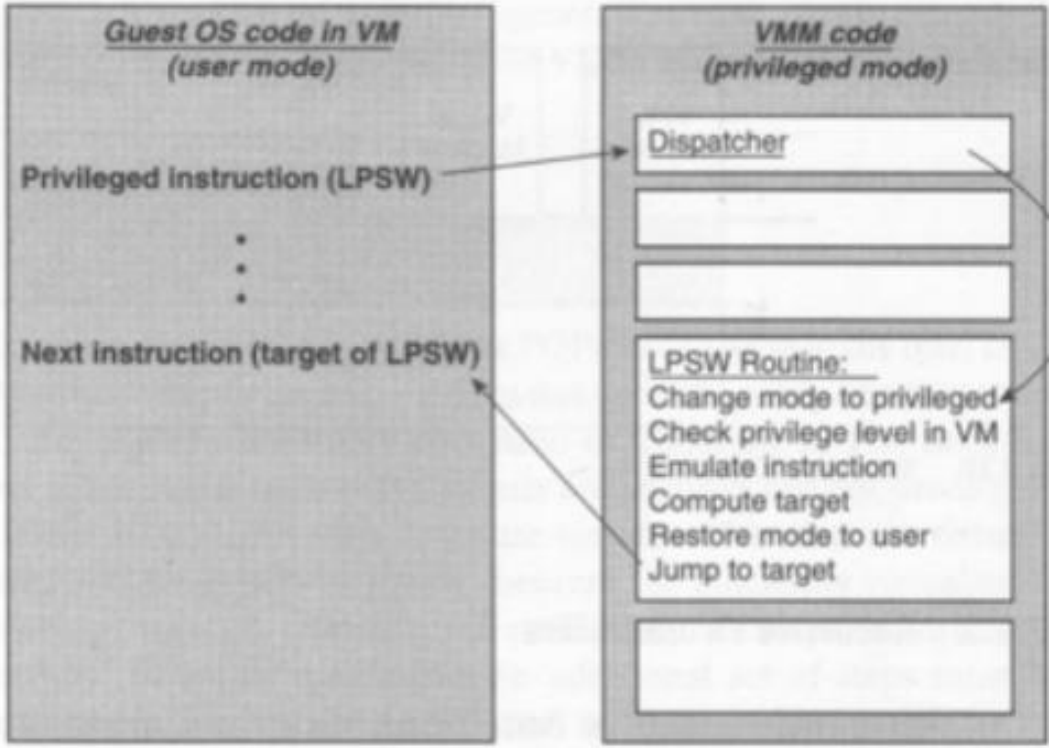
Virtualizing individual resources in system VMs

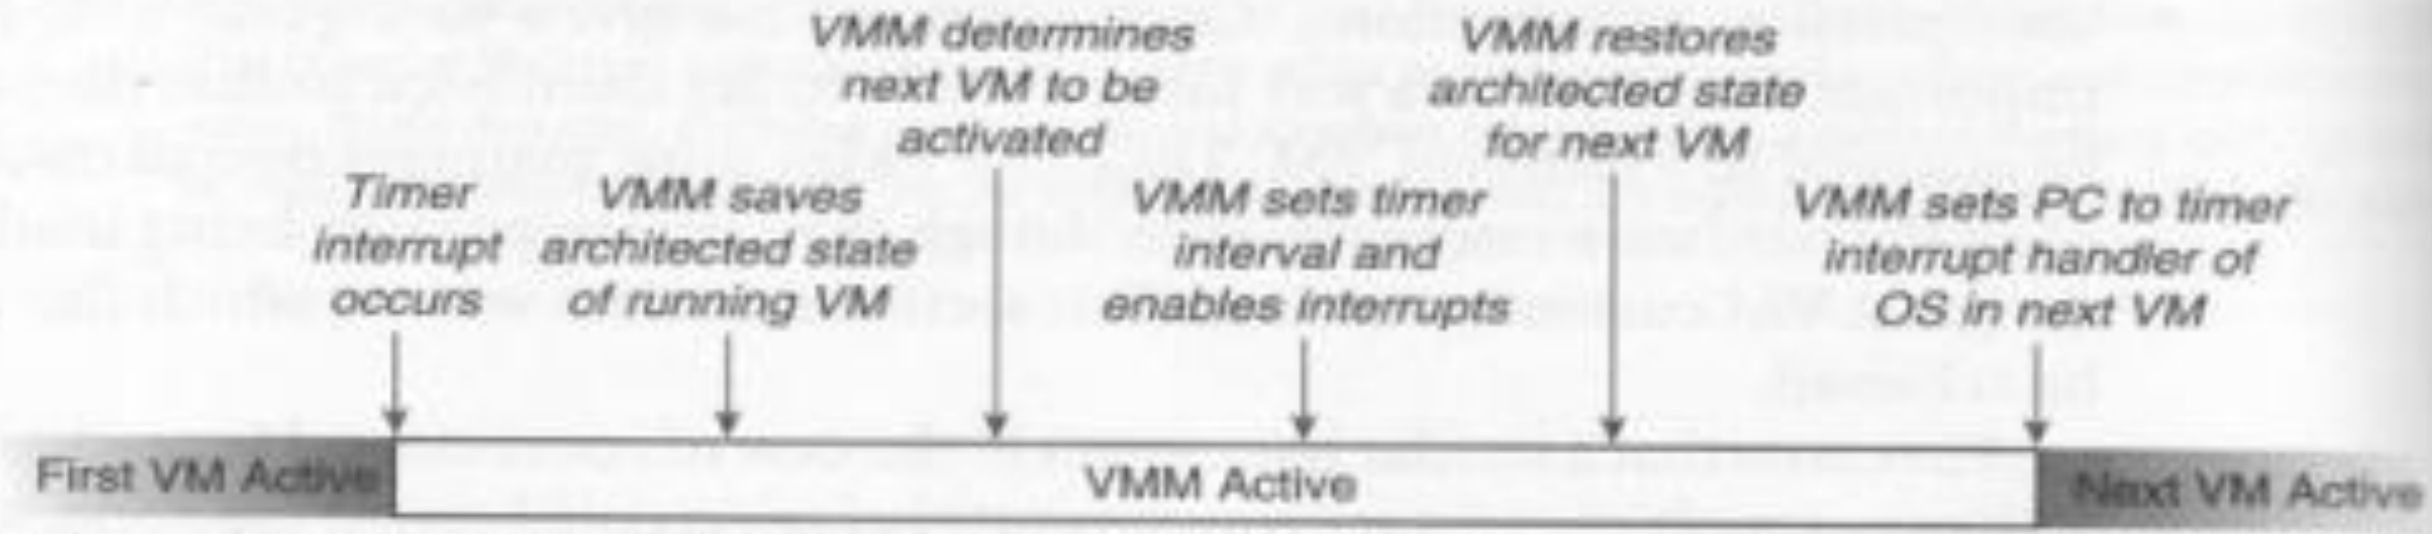
CPU Virtualization for VMs

- Each VM sees a set of “virtual CPUs”
- Hypervisors must emulate privileged instructions issued by guest OS.
- Modern ISAs provide special interfaces for Hypervisors to run VMs
  - Intel provides the VTx interface
  - AMD provides the AMD-v interface
- These special ISA interfaces allow the Hypervisors to efficiently emulate privileged instructions executed by the guest OS.
- When guest OS executes a privileged instruction
  - Hardware traps the instruction to the hypervisor
  - Hypervisor checks whether instruction must be emulated.
  - If so, Hypervisor reproduces the effect of the privileged operation.

Execution of Privileged Instruction by Guest





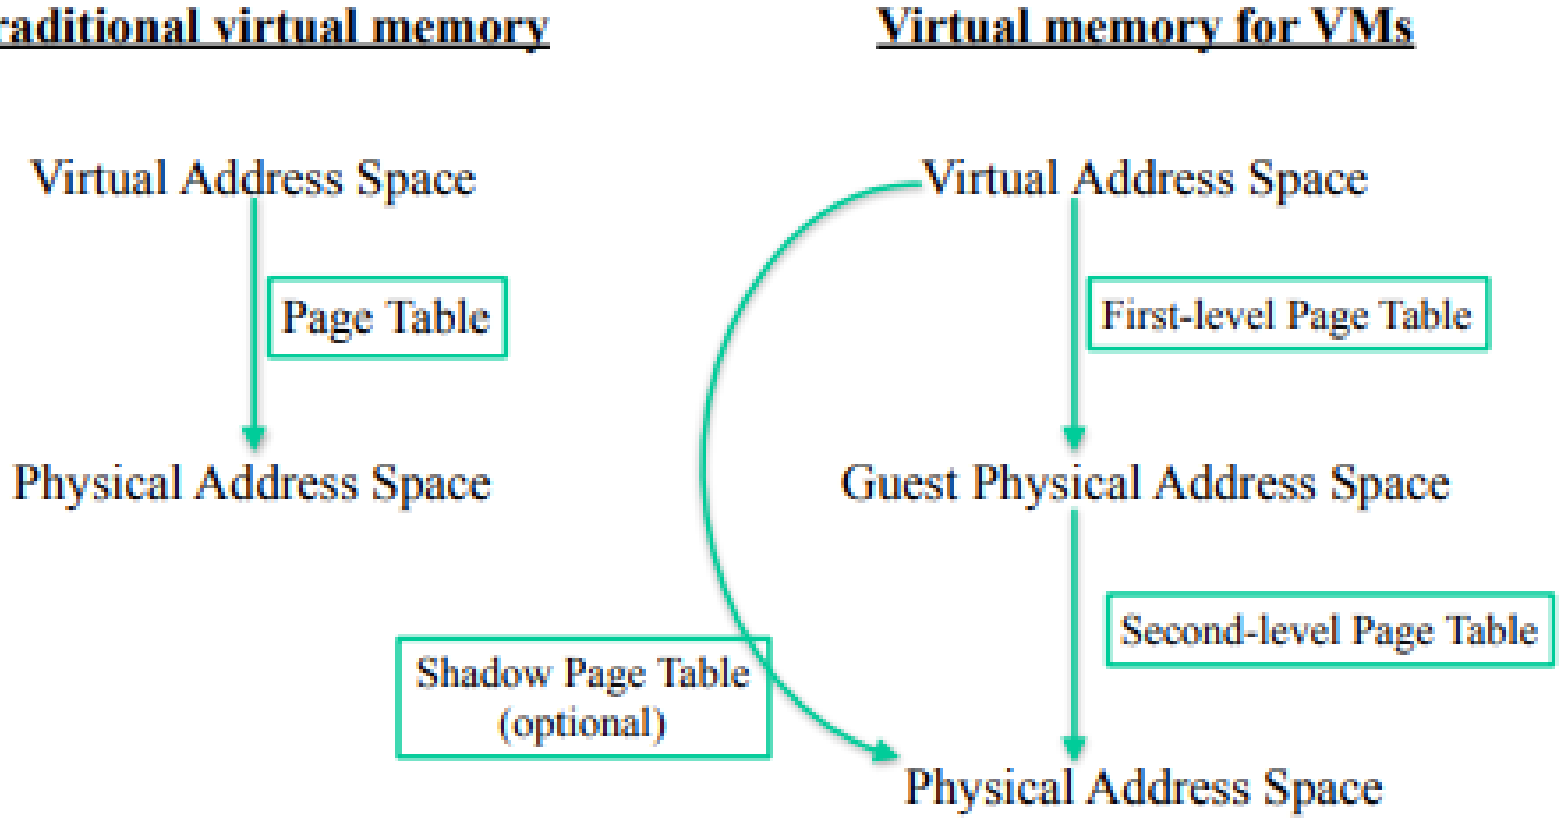


ure 8.4 Actions Taken by the VMM in Retiring One Virtual Machine and Activating the Next Virtual Machine

Resource Control

- Issue: How to retain control of resources in the Hypervisor?
- Timer interval control performed by Hypervisor
- Also, guest OS is not allowed to read the timer value
  - Guest OS sees a virtual interval timer
- Hypervisor also gains control whenever guest OS executes privileged instructions

Memory Virtualization for VMs



- Guest OS in each VM sees a “guest”-physical address (GPA) space instead of the physical addresses
- Often hardware supports two-level page tables
  - EPT in Intel VT-x and NPT in AMD-v
- When hardware doesn’t, then Hypervisor needs to emulate two-level page tables using “shadow page tables”

I/O Virtualization for VMs

- Hypervisor provides a virtual version of each physical device
- I/O activity directed at the virtual device is trapped by Hypervisor and converted to equivalent request for the physical device.
- Options:
  - Device emulation
    - Hypervisor traps and emulates each I/O instruction from Guest in Hypervisor.
    - Throughput is very slow.
    - Difficult to emulate the effect of combinations of I/O instructions.
  - Para-virtual devices
    - Special device drivers inserted in guest OS to talk to Hypervisor.
    - Most common.
  - Direct device access
    - Allow the VM to directly access physical device.
    - Fastest option but not scalable.
    - Requires IOMMU and VT-d support from hardware

Thank you!
